

ABSTRACT

A digital camera includes an input detection section, which has an input detection plane, that detects a touching position of a finger of an operator and a sliding speed of the finger, a controller that computes a vibration pattern based on the sliding speed detected by the input detection section, and a vibration section that vibrates the input detection plane based on the vibration pattern thus computed. The controller computes a vibration pattern of the input detection plane to generate vibrations from its low frequency and small amplitude to its high frequency and large amplitude, as the finger goes away from a position where it has touched the input detection plane.
